

ISL68200DEMO1Z Demonstration Board User Guide

The [ISL68200](#) is a single-phase synchronous buck PWM controller featuring Intersil's proprietary R4™ Technology, which has extremely fast transient performance, accurately regulated frequency control and all internal compensation. The ISL68200 supports a wide 4.5V to 24V input voltage range and a wide 0.5V to 5.5V output range. It includes programmable functions and telemetries for easy use and high system flexibility using SMBus, PMBus, or I²C interface. See the ISL68200 datasheet for more details.

The ISL68200DEMO1Z is a 6-layer board demonstrating a compact 17mmx17mm 20A synchronous buck converter. Transient performance, fault protections, DC/AC regulations, PMBus programming, power sequencing, margining and other features can be evaluated using this board.

The PMBus dongle (ZLUSBEVAL3Z), i.e., USB-to-PMBus™ adapter, and USB cable are included in the demonstration kit. Intersil's evaluation software can be installed from Intersil's website and evaluate the full PMBus functionality of the part using a PC running Microsoft Windows 7 or 8.

Key Features

- 20A synchronous buck converter with PMBus control
- On-board transient load with adjustable di/dt
- Configurable through resistor pins
- Cascadeable PMBus connectors
- Integrated LDOs for single rail solution
- Enable switch and power-good indicator
- All ceramics solution with SP capacitor footprint option

Target Specifications

- V_{IN} = 4.75V to 14.5V
- V_{OUT} = 1V/20A full load
- f_{SW} = 400kHz
- Peak efficiency:
 - 89% at 12A/1V_{OUT}/12V_{IN}
 - 94% at 6A/1.8V_{OUT}/5V_{IN}
- Output regulation: 1V ±8mV
- I/O capacitor rating: C_{IN} - 16V; C_{OUT} - 4V
- Compact size: 17mmx17mm
- With or without PMBus/SMBus/I²C Capability

FIGURE 3. DEMONSTRATION BOARD BOTTOM VIEW

Demonstration Board Description

The ISL68200DEMO1Z provides all circuitry required to demonstrate the key features of the ISL68200. A majority of the features of the ISL68200, such as optimal transient response with Intersil's R4™ Modulator, 8-bit programmable boot voltage levels, selectable switching frequency in continuous conduction mode, selectable PFM operation option for improved light-load efficiency, power-good monitor for soft-start and fault detection, over-temperature protection, output over-current and short-circuit protection and output overvoltage protection are available on this demonstration board.

[Figure 1](#) shows a simplified schematic diagram of the ISL68200DEMO1Z board. [Figure 6](#) shows the detailed 20A buck solution schematics, while [Figure 7](#) shows the I/O connectors, auxiliary circuits and on-board transient circuits. [Figures 8](#) through [30](#) show typical performance data and [Figures 31](#) through [36](#) show the PCB board layout. The default programming pins setting is given on the upper right corner of [Figure 7](#), and the Bill of Materials (BOM) is included for reference beginning on [page 9](#).

The ISL68200DEMO1Z board can run by itself without a series bus communication. The operational configuration is fully programmable via programming pins (PROG1-4).

The ISL68200 however, utilizes the PMBus/SMBus/I²C protocol and provides the flexibility for digital power management and performance optimization prior to finalizing the hardware configuration on the programming pins.

The buck regulator in the ISL68200DEMO1Z board is a single input rail design, i.e., everything is biased by the input supply (typically 12V). The resistor divider on the EN pin (R₄ and R₁₂) can set the input supply undervoltage protection level and its hysteresis. The "ENABLE" switch is a hardware operational control, alternately, the series bus ON_OFF_CONFIG and OPERATION commands can be used for software operational control.

Furthermore, an on-board transient load, as shown in [Figure 7](#), with both di/dt and load step amplitude is controlled by a function generator. Since this auxiliary circuit draws more than 10A of bias current, the jumper on JP5 should be removed for accurate efficiency measurement.

Intersil's evaluation software is compatible with Windows 7 or 8 operating systems and can be used to evaluate the series bus functionality of the ISL68200. The software and user guide can be found in following Intersil website:

<http://www.intersil.com/powernavigator>

Quick Start Guide

Stand-Alone Operation

1. Set ENABLE switch to "OFF" position.
2. Connect a power supply (off) to input connectors (J4-VIN and J2-GND).
3. Set input power supply voltage level (no more than 15V) and current limiting (no more than 1A for 0A load).
4. Turn the power supply on.
5. Set ENABLE switch to "ON" position.
6. Increase power supply current limit enough to support more than the full load.
7. Apply load to output connectors (J1-VOUT and J2-SGND).
8. Monitor operation using an oscilloscope.

PMBus Operation

1. Connect supplied Intersil's dongle J9.
2. Connect supplied USB cable from computer to the dongle.
3. After the input power supply turns on, open the PowerNavigator evaluation software.
4. Select detected ISL68200 device (Address - 60h) and follow Intersil's PowerNavigator™ operation guide.
5. Monitor and configure the board using PMBus commands in the evaluation software.

Configuration

The default programming pins setting of the ISL68200DEMO1Z board can be found at the resistor reader table on the upper right corner of [“ISL68200DEMO1Z Schematics” on page 7](#) or read back via Intersil’s PowerNavigator™ software. Each PMBus command can be loaded or programmed via the PowerNavigator™ software. Note that ISL68200 does not have NVM to store the operational configuration, which can however be set by the resistor programming pins (PROG1-4) or programmed by the series bus master before powering up. If a series bus master is available in the system, the ISL68200-based rail can be fully controlled via software for the power-up/down sequencing and operational configuration without a soldering iron.

Load Transient

The on-board transient load can be controlled by a function generator, whose inputs are connected to FG_DRIVE2 and FG_GND2. The function generator’s output is terminated by R42 at the input terminal, while its amplitude and dV/dt set the load amplitude and di/dt on the 50mΩ load (RLT1//RLT2). The transient load can be monitored with a scope probe on TP15. Note that the duty cycle of applied load should be less than 10% duty cycle with <10ms pulse width to keep the average power of RLT1/RLT2 less than its power rating.

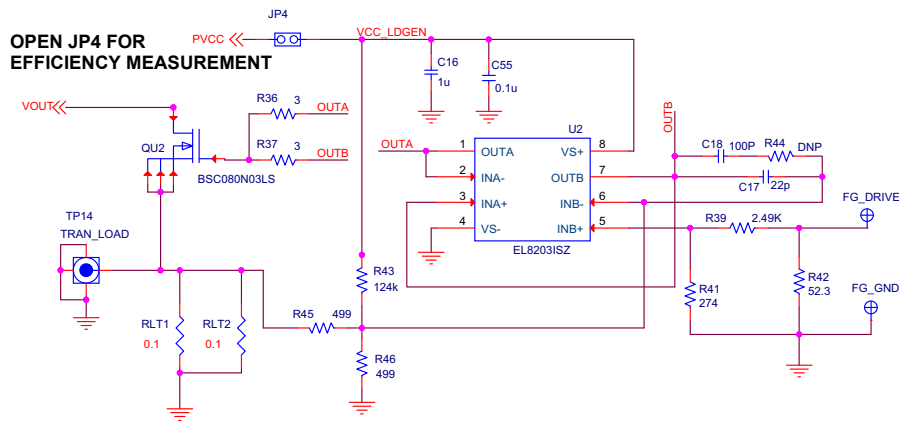

FIGURE 4. LOAD TRANSIENT

FIGURE 5. ISL68200 DEMONSTRATION KIT SET-UP

Design Modifications

When modifying the design, it will require a new set of L/DCR matching for different inductor, divider on the PROG pins for different operational configuration, RSEN1 for OCP, and I_{OUT} network for accurate digital I_{OUT}; higher input capacitor rating to support higher than 16V input, higher output capacitor rating to support higher than 4V output. Refer to [ISL68200](#) datasheet and [PowerNavigator™](#) software for proper design modifications including L/DCR matching, thermal compensation, OCP and digital I_{OUT} fine tuning.

Two examples are provided in [Table 1](#), showing the recommended design modifications to accommodate the application cases with 5V and 3.3V output voltages. Some

fine-tune might be needed depending upon the rework and final layout design.

For the 5V input voltage applications with $4.5V < V_{IN} < 5.5V$ requirement, the “VIN”, “VCC”, “PVCC” and “7VLDO” pins should be shorted together, to connect with the input supply for optimal performance; R₁₂ should be removed as well.

Note that all devices in the same bus should set different addresses for unique identification and proper communication. JP2, JP3, JP9 and JP10 connectors are designed to cascade many Intersil's solutions for easy communication and system evaluation prior to the system integration and design.

TABLE 1. DESIGN EXAMPLES

REFERENCE DESIGNATOR	5.0V AT 16A	3.3V AT 16A	3.3V AT 30A	COMMENTS

R14	TBD	TBD	TBD	Pull-up value depends upon final layout design

NOTE:

1. Some fine-tune might be needed depending upon the rework and final layout design.

Design and Layout Considerations

To ensure a first pass design, the schematics design must be done correctly and the board must be carefully laid out.

As a general rule, power layers should be close together, either on the top or bottom of the board, with the weak analog or logic signal layers on the opposite side of the board or internal layers. The ground-plane layer should be in between the power layers and the signal layers to provide shielding, often the layer below the top and the layer above the bottom should be the ground layers.

There are two sets of components in a DC/DC converter, the power components and the small signal components. The power components are the most critical because they switch large amount of energy. The small signal components connect to sensitive nodes or supply critical bypassing current and signal coupling.

The power components should be placed first and these include MOSFETs, input and output capacitors and the inductor. Keeping the distance between the power train and the control IC short helps keep the gate drive traces short. These drive signals include the LGATE, UGATE, GND, PHASE and BOOT.

When placing MOSFETs, try to keep the source of the upper MOSFETs and the drain of the lower MOSFETs as close as thermally possible. Input high frequency capacitors should be placed close to the drain of the upper MOSFETs and the source of the lower MOSFETs. Place the output inductor and output capacitors between the MOSFETs and the load. High frequency output decoupling capacitors (ceramic) should be placed as close as possible to the decoupling target, making use of the shortest connection paths to any internal planes. Place the components in such a way that the area under the IC has less noise traces with high dV/dt and di/dt , such as gate signals, phase node signals and VIN plane.

[Tables 2](#) and [3](#) provide design and layout checklist that the designer must pay attention to.

TABLE 2. DESIGN AND LAYOUT CHECKLIST

PIN NAME	NOISE SENSITIVITY	DESCRIPTION
EN	Yes	There is an internal 1 μ s filter. Decoupling the capacitor is NOT needed, but if needed, use a low time constant one to avoid too large a shutdown delay.
VIN	Yes	Place 16V+ X7R 1 μ F in close proximity to VIN pin and the system ground plane.
7VLDO	Yes	Place 10V+ X7R 1 μ F in close proximity to 7VLDO pin and the system ground plane.
VCC	Yes	Place X7R 1 μ F in close proximity to VCC pin and the system ground plane.

TABLE 2. DESIGN AND LAYOUT CHECKLIST (Continued)

PIN NAME	NOISE SENSITIVITY	DESCRIPTION
SCL, SDA	Yes	50kHz to 1.25MHz signal when the SMBus, PMBus, or I ² C is sending commands. Pairing up with SALERT and routing carefully back to SMBus, PMBus or I ² C master. 20 mils spacing within SDA, SALERT and SCL; and more than 30 mils to all other signals. Refer to the SMBus, PMBus or I ² C design guidelines and place proper terminated (pull-up) resistance for impedance matching. Tie them to GND when not used.
SALERT	No	Open-drain and high dv/dt pin during transitions. Route it in the middle of SDA and SCL. Tie it to GND when not used.
PGOOD	No	Open-drain pin. Tie it to ground when not used.
RGND, VSEN	Yes	Differential pair routed to the remote sensing points with sufficient decoupling ceramics capacitors and not across or go above/under any switching nodes (BOOT, PHASE, UGATE, LGATE) or planes (VIN, PHASE, VOUT) even though they are not in the same layer. At least 20 mils spacing from other traces. DO NOT share the same trace with CSRTN.
CSRTN	Yes	Connect to the output rail side of the output inductor or current sensing resistor pin with a series resistor in close proximity to the pin. The series resistor sets the current gain and should be within 40 Ω and 3.5k Ω . Decoupling (~0.1 μ F/X7R) on the output end (not the pin) is optional and might be required for long sense trace and a poor layout.
CSEN	Yes	Connect to the phase node side of the output inductor or current sensing resistor pin with L/DCR or ESL/R _{SEN} matching network in close proximity to CSEN and CSRTN pins. Differentially routing back to the controller with at least 20 mils spacing from other traces. Should NOT cross or go above/under the switching nodes [BOOT, PHASE, UGATE, LGATE] and power planes (VIN, PHASE, VOUT) even though they are not in the same layer.
NTC	Yes	Place NTC 10k (Murata, NCP15XH103J03RC, $\beta = 3380$) in close proximity to the output inductor's output rail, not close to MOSFET side; the return trace should be 20 mils away from other traces. Place 1.54k Ω pull-up and decoupling capacitor (typically 0.1 μ F) in close proximity to the controller. The pull-up resistor should be exactly tied to the same point as VCC pin, not through an RC filter. If not used, connect this pin to VCC.
IOUT	Yes	Scale R such that IOUT pin voltage is 2.5V at 63.875A load. Place R and C in general proximity to the controller. The time constant of RC should be sufficient as an averaging function for the digital IOUT. An external pull-up resistor to VCC is recommended to cancel IOUT offset at OA load.

User Guide 067

TABLE 2. DESIGN AND LAYOUT CHECKLIST (Continued)

PIN NAME	NOISE SENSITIVITY	DESCRIPTION
PROG1-4	No	Resistor divider must be referenced to VCC pin and the system ground; they can be placed anywhere. DO NOT use decoupling capacitors on these pins.
GND	Yes	Directly connect to low noise area of the system ground. The GND PAD should use at least 4 vias. Separate analog ground and power ground with a 0Ω resistor is highly NOT recommended.
LGATE	No	Low-side driver output and short and wide trace in between this pin and MOSFET gate pin as possible. High dV/dt signals should not be close to any sensitive signals.
UGATE	No	High-side driver output and short and wide trace in between this pin and MOSFET gate pin as possible. High dV/dt signals should not be close to any sensitive signals.
BOOT, PHASE	Yes	Place X7R 0.1μF or 0.22μF in proximity to BOOT and PHASE pins. High dV/dt signals should not be close to any sensitive signals.
PVCC	Yes	Place X7R 4.7μF in proximity to PVCC pin and the system ground plane.

TABLE 3. TOP LAYOUT TIPS

NUMBER	DESCRIPTION
1	The layer next to controller (top or bottom) should be a ground layer. Separate analog ground and power ground with a 0Ω resistor is highly NOT recommended. Directly connect GND PAD to low noise area of the system ground with at least 4 vias.
2	Never place controller and its external components above or under VIN plane or any switching nodes.
3	Never share CSRTN and VSEN on the same trace.
4	Place the input rail decoupling ceramic capacitors closely to the high-side FET. Never use only one via and a trace to connect the input rail decoupling ceramics capacitors; must connect to VIN and GND planes.
5	Place all decoupling capacitors in close proximity to the controller and the system ground plane.
6	Connect remote sense (VSEN and RGND) to the load and ceramic decoupling capacitors nodes; never run this pair below or above switching noise plane.
7	Always double check critical component pinout and their respective footprints.
